Anatomy and Physiology

The skeletal system is composed of the bones and related structures that aid body movement. It is divided into two major parts: the axial skeleton and the appendicular skeleton (Figure 2.1).

The **axial skeleton** consists of the bones along the **axis**, or central line, of the human body. The axial skeleton consists of the skull, facial bones, sternum (breastbone), ribs, and vertebral column.

The **appendicular skeleton** contains the bones in the **appendages** of the body, as well as the structures that connect the appendages to the axial skeleton. Specifically, the appendicular skeleton comprises the shoulder girdle, the arm, wrist, and hand bones; the pelvic girdle; and the leg, ankle, and foot bones.

Functions of Bone

The skeletal system serves five important functions in the human body.

- **Support**—The skeletal system provides structure and shape for the body.
- **Protection**—The skeletal system surrounds and protects the internal organs.
- **Mineral storage**—Calcium and phosphorus, two minerals that the body needs for important regulatory functions, are stored inside the bones.
- **Blood cell formation**—Red blood cells are manufactured in the bone marrow.
