

Medicinal chemistry deals with the design, optimization and development of chemical compounds for use as drugs.

- Functional groups play a significant role in:
  - Water/lipid solubility
  - Route of administration
  - Ability to interact with the specific biological target.
  - Mechanism (mode or method) of action
  - Route of metabolism and elimination
  - Duration of action
  - Suitability for specific therapeutic situations
  - Tendency to cause adverse effects or drug interactions.
- These concepts that should always be considered when examining a drug molecule:
  1. Every atom within the structure belongs to some functional group.
  2. Within a drug molecule, some functional groups may be more "important" than others. The opposite may be true for a different drug molecule.
  3. Altering functional groups can enhance activity, increase absorption, decrease adverse effects, and provide other therapeutic benefits.
- These major chemical properties that need to be analyzed for every functional group:
  1. **Electronic effect:** The components that comprise the overall electronic effect of a functional group are **induction** and **resonance**.
    - a. Measured by a functional group's ability to donate its electrons to adjacent atoms or functional groups.
  2. **Solubility effect:** Overall solubility is a composite sum of all the functional groups found as part of a drug molecule.
    - b. **Steric effect:** Each functional group has a finite size and steric dimension; this contributes to the overall conformation and thus the 3-D shape of a given drug.
- The three major chemical properties combined need to be considered when evaluating the overall pharmacodynamic and pharmacokinetic properties of new drug-drug molecule.

### ELECTROCOMPACTIVITY-KEY POINTS

- F, Cl, Br, and I are the most electronegative elements.
- O will always attract electrons to it, unless it is attached to a F.
- All the halogens (F, Cl, Br, and I) as well as O and N will attract electrons away from C.
- C will slightly attract electrons away from H (inductive effect).
- The difference in electronegativity causes a **dipole**.

See how brilliant you

- Overall water and/or lipid solubility of a drug molecule affects its route(s) of administration, distribution within the body, metabolism, duration of action, and route(s) of elimination.

- Terms to know:
  - **Hydrophobicity (a.k.a. lipophilicity):** How water-avoiding (i.e., oil-loving) is a drug molecule is
  - **Hydrophilicity (a.k.a. lipophobicity):** How water-loving (i.e., oil-avoiding) is a drug molecule is
- The contribution to solubility by a functional group may be increased or decreased depending upon adjacent groups.
- Water soluble functional groups:
  - Enhance water solubility, often referred to as hydrophilic groups
- The two major properties that contribute to water solubility:
  - Whether the group is or can be ionized
    - Either positive (+) or negative (-)
  - **EN:** Quaternary amine — no matter what pH the molecule finds itself in, it will always have a + charge.
  - The group's ability to hydrogen bond with water

### Säure- & Salzelektrolyse

- The addition of a strategically useful functional group can:
  - Increase selectivity for its biological target
  - Enhance binding interactions with its biological target
  - Cause favorable alterations in the rate of metabolism
- The acidic/basic nature of a drug molecule influences its chemical, pharmaceutical, and therapeutic properties.
- If a functional group can be ionized at a certain pH, its water solubility will increase.
  - While this helps the gastrointestinal (GI) tract dissolve the molecule, the unionized form (without a charge) is better for passage through the lipid membrane.
- Ionization: Equilibrium process that allows for functional groups to form electrostatic interactions with target receptors, transport proteins, enzymes, and other endogenous biological targets.
  - Electrostatic (i.e., ionic) interactions are the strongest noncovalent bonds.
- Drug molecules can interact with plasma proteins (usually via electrostatics).
  - This sequesters them from metabolic/excretion pathways and extends the duration of action.
- The human serum albumin is a major transporter of drug molecules but is nonspecific. It generally binds acid drug molecules to a greater extent than basic drug molecules.
  - Albumin also binds hydrophobic compounds more tightly than hydrophilic ones.
- What if you are taking two different drugs and both contain an acidic functional group?
  - Plasma protein displacement interactions can occur.
  - This could greatly affect the half-life of the drug, particularly when the drug is 90% plasma protein bound.

- Drug molecules that are highly ionized are more water soluble, so they need less metabolism to be eliminated.
- There are specific transport proteins of certain organic acids within the renal tubules that actively secrete acidic molecules:
  - From the plasma to the urine:
    - This decreases the half-life of the drug molecules.
    - From the urine to the plasma.
    - This increases the half-life of the drug molecules.

**pH & pK**

- $\text{pH} = -\log[\text{H}^+]$ 
    - Refers to the solution, not a functional group
    - Indicates how many "free"  $\text{H}^+$  there are in the solution
- EX: pH of 0.1 M  $\text{H}^+$

- Affected by steric and electronic effects
- Can be used to compare the relative acidity of functional groups
  - Rule 1: Lower  $pK_a$  value = stronger acid (wants to lose the H)
  - Rule 2: Higher  $pK_b$  value = stronger conjugate base/weak(er) acid (wants to gain the H)

- Low  $pK_a$ : Reaction is to the right
  - High  $pK_a$ : Reaction is to the left
- $pK_a = -\log(K_a)$

- Used to calculate the:
  - pH change in buffered solutions
  - pH change in the molar ratio of salt to acid concentrations needed to prepare a buffer solution at a certain pH
  - Percent ionization of a functional group at a certain solution pH

**EX:** Flurbiprofen's functional group has a  $pK_a$  of 4.5, so it must be carboxylic acid. Will it be primarily protonated or unprotonated if it is in the urine at pH 5.5?

$$pH - pK_a = \log \left[ \frac{\text{Unprotonated form}}{\text{Protonated form}} \right]$$

$$-3.50 = -4.50 + \log \left[ \frac{[\text{Unprotonated form}]}{[\text{Protonated form}]} \right]$$

$$L.R. = \log \left( \frac{[\text{Unprotonated form}]}{[\text{Protonated form}]} \right)$$
