**Development of Methods for Assessment of Gliding Parachute Applications**, 1982 In order to assess the possible utility of gliding parachutes it was necessary to develop a set of methods for predicting behavior of gliding parachutes The extent of agreement between simulation and flight data indicates that the primary factors included

in the longitudinal stability analysis and in the 6DOF simulation are correct Although the stability analysis predicts only steady state behavior it forms the basis required for analysis of dynamic behavior in the body fixed XZ plane The agreement seen in descent rate would not be possible with an invalid stability model Of course in turning flight during the response immediately following the deflection other factors such as the assumed spanwise distribution of lift and drag become predominant The agreement in yaw rate best illustrates correctness of this aspect of the 6DOF model The mechanics driving motion during a spin are quite difficult to understand however the agreement shown in the descent rate indicates that the mass ratios assumed are accurate and further justifies the assumption of spanwise distribution of lift and drag In further development activities on gliding parachute systems the 6DOF model will serve to guide exploratory work and will be updated for more accurate application to different canopies and to larger systems
